Data Exploration: are there differences between warmed vs. ambient plots when we account for species?

Starting with KBS

First, checking for normality in raw data. This is a little weird to do because each row in the dataframe is a species-plot combo, so you're missing the influence of species below. Instead, re-run this on plot-level half cover date (re-compute this in `plant_comp_clean_L0.R` to get that variable first). It's also not going to tell you about normality once you fit a model to these data - that's when you really need to investigate the residuals.

Note that since this change, some of the code below breaks because the variable name changed. Also, there seem to be some errors popping up with `qqPlot`, suggesting that something else changed when this new variable was created. Check

```
# remove species, origin, duration, growth
# habit, spp_half_cover_date - again, this should be done in
# other script preceding this one
green_kbsp <- subset(green_kbsp, select = c("plot_half_cover_date",
      "min_green_date", "plot", "year", "state", "insecticide",
      "site", "year_factor"))
head(green_kbsp)
```

```
##   plot_half_cover_date min_green_date plot year  state insecticide site
## 1                   232              81  A1 2016  ambient  no_insects kbs
## 2                   101              61  A1 2017  ambient  no_insects kbs
## 3                   235              59  A1 2018  ambient  no_insects kbs

# looks like the 225 spike is from 2018 and 2020 - what's
# going on here is that you are treating all species-plot
# records as independent observations, so the influence of
# species differences is likely coming through here.
kbs_2018 <- subset(green_kbs, year == 4) # many records on 235
kbs_2020 <- subset(green_kbs, year == 6) # records from 227 & 228
```

Leverage plots and detecting Outliers. <https://www.statmethods.net/stats/riagnostics.html>

These illustrate whether certain data points have more leverage (more influence), and thus could be outliers. It's a way of detecting outliers. Leverage plots can help identify whether a point has high or low influence, based on its leverage and residual and determining model fit with and without the point in question. Ultimately you decide whether the points are outliers or not, based on the knowledge of the system and how much it changes the model when included vs. excluded from the data used to fit the model. Here is a good overview of the combination of leverage and residual: scroll down to sections beginning at "13.3 Unusual Observations": <https://davidalpiatz.github.io/appliedstats/model-diagnostics.html>

```
# checking fit for date as a function of state and species -  
# bringing in species here makes it obvious that that is  
# explaining some of the variation compared with the  
# state-only model you had previously.

Leverage Plots

Normal distribution after accounting for species - we will be using species as a random effect to account for their variation. Set up some linear mixed effects models to evaluate. From Ben Bolker: “The traditional view of random effects is as a way to do correct statistical tests when some observations are correlated. ... Random effects are especially useful when we have (1) lots of levels (e.g., many species or blocks), (2) relatively little data on each level (although we need multiple samples from most of the levels), and (3) uneven sampling across levels. People sometimes say that random effects are “factors that you aren’t interested in.” This is not always true. While it is often the case in ecological experiments (where variation among sites is usually just a nuisance), it is sometimes of great interest.” In our case, variation among plots is a nuisance, and not something we’re interested in. For some questions, variation among species is also a nuisance for us. It’s possible that variation among years is a nuisance if we only care about warm vs. ambient, but I think time is an interesting variable to consider with this study.

We should also think about how we’re treating year. Some of the models have a state * year interaction as a fixed effect, which means that the warming or ambient treatment could affect the half_cover_date differently over time (there would be a different slope for each state in the relationship between half_cover_date (y) and year (x)). If we just had state + year, the states would have the same slope, indicating that they have no interaction in their effect on half_cover_date (but they could still have different intercepts).

```
# Interaction plot (ignore for now the repeated measures with  
# species); see:  
# https://cran.r-project.org/web/packages/interactions/vignettes/interactions.html  
# and: https://interactions.jacob-long.com/  
  
fit3 <- lm(plot_half_cover_date ~ state + year, data = green_kbsp)  
interact_plot(fit3, pred = year, modx = state)
```

```
## Warning: year and state are not included in an interaction with one another in the  
## model.
```

```
fit4 <- lm(plot_half_cover_date ~ state * year, data = green_kbsp)
interact_plot(fit4, pred = year, modx = state)
```

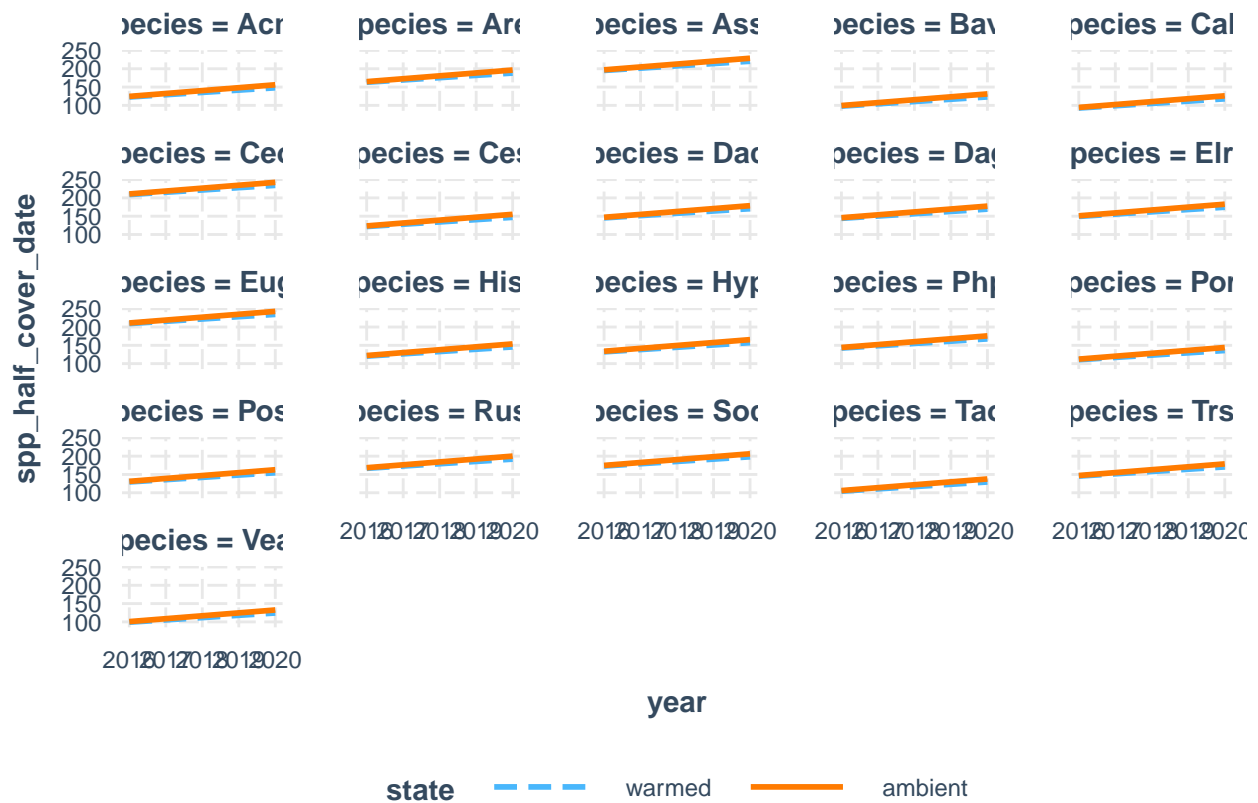

```
fit5 <- lm(spp_half_cover_date ~ state + year + species, data = green_kbs)
interact_plot(fit5, pred = year, modx = state)
```

```
## Warning: year and state are not included in an interaction with one another in the
## model.
```

```
fit6 <- lm(spp_half_cover_date ~ state * year + species, data = green_kbs)
interact_plot(fit6, pred = year, modx = state, mod2 = species)
```

```
## Warning: year and state and species are not included in an interaction with one
## another in the model.
```

```
fit7 <- lm(min_green_date ~ state + year + species, data = green_kbs)
interact_plot(fit7, pred = year, modx = state)
```

```
## Warning: year and state are not included in an interaction with one another in the
## model.
```

```
fit8 <- lm(min_green_date ~ state * year + species, data = green_kbs)
interact_plot(fit8, pred = year, modx = state, mod2 = species)
```

```
## Warning: year and state and species are not included in an interaction with one
## another in the model.
```

Mixed Effects Models:

```
# Start by replicating (almost) what we did in the Decologia
# 2018 paper. The only difference here is that we have
# multiple years, so we are also including year as a fixed
# effect and as an interactive term. Our goal here is to find
# a model that is the best fit to the data. We also want to
# find a model that is the most parsimonious (one that has
# the fewest parameters).
```

```
# Do we need to include plot as a random effect with the KBS
# models?
mod1 <- lmer(spp_half_cover_date ~ state * year + insecticide *

Random effects

mod4 (and mod7) are pretty complex in terms of interpretation (they actually don't have many parameters though). We could consider an alternative model that's simpler to understand and also one that provides more insight about the species. That would be something like this: We're going to use lmerTest for this example so you can see how to run through post-hoc tests.

```
library(lmerTest)
```

```
##
```

```
## Attaching package: 'lmerTest'
```

```
## The following object is masked from 'package:lme4':
```

```
##
```

```
## lmer
```

```
## The following object is masked from 'package:stats':
```

```
##
```

```
## step
```

```
mod8 <- lmer(spp_half_cover_date ~ state + species + (1 + year |  
plot), green_kbs, REML = FALSE)
```

```
## boundary (singular) fit: see ?isSingular
```

```
## Warning: Model failed to converge with 1 negative eigenvalue: -3.2e-01
```

```
anova(mod7, mod8) # model 8 is a better fit to data
```

```

Random effects

*# You could now run some post hoc tests on these (see:
<https://stats.stackexchange.com/questions/169543/output-of-fixed-effects-summary-in-lmer-test-in-r-and>*

*# Here are some other options for plotting these plots above:
<https://stackoverflow.com/questions/31075407/plot-mixed-effects-model-in-ggplot>*

*# Here's another approach:
<https://stats.stackexchange.com/questions/98958/plots-to-illustrate-results-of-linear-mixed-effect-mo>
Not quite working yet:*

```
newdat <- expand.grid(state = unique(green_kbs$state), year = c(min(green_kbs$year),
  max(green_kbs$year)), insecticide = unique(green_kbs$insecticide))
p <- ggplot(green_kbs, aes(x = year, y = spp_half_cover_date,
  colour = state, shape = insecticide)) + geom_point(size = 3) +
  geom_line(aes(y = predict(mod5), group = species, size = "species")) +
  geom_line(data = newdat, aes(y = predict(mod5, level = 0,
    newdata = newdat), size = "Population")) + scale_size_manual(name = "Predictions",
    values = c(species = 0.5, Population = 3)) + # facet_wrap(~insecticide) +
theme_bw(base_size = 22)
# print(p)
```

*# New version of our model incorporating interaction term and
species within year so that there is a separate intercept
and slope for each species. The issue here is that there
are some species that are not found each year. Easiest to
remove those from another version of this dataframe before
running below. Otherwise, it's not a balanced design.*

```
mod4 <- lmer(spp_half_cover_date ~ state * year + (1 + year |
```

```
species), green_kbs)
```

```
## Warning: Some predictor variables are on very different scales: consider

ORIGINAL CODE BELOW; not edited by Phoebe

Seeing what other distribution could fit

```
descdist(green_kbs$spp_half_cover_date, discrete = FALSE)
```

```
## summary statistics
## -----
## min:  59   max:  289
## median: 127
## mean: 154.2169
## estimated sd: 57.9311
## estimated skewness: 0.5680173
## estimated kurtosis: 2.125259
```

While uniform looks the closest, I'll try poisson

```
fit <- lm(spp_half_cover_date ~ state, data = green_kbs)
residual <- fit$residuals
hist(residual, main = "Raw residuals")
```

```
pois <- glm(spp_half_cover_date ~ state, data = green_kbs, family = "poisson")
hist(pois$residuals, main = "Poisson glm residuals")
```

Poisson glm residuals

Below I try a few different generalized linear models with poisson distribution:

An interaction between state and year, plus insecticide as a fixed effect and species and plot as random effects

```
moda <- glmer(spp_half_cover_date ~ state * year + insecticide +  
  (1 | species) + (1 | plot), data = green_kbs, family = poisson)
```

```
## Warning: Some predictor variables are on very different scales: consider

State and insecticide as fixed effects & year, species and plot as random effects

```
modc <- glmer(spp_half_cover_date ~ state + insecticide + (1 |  
  year) + (1 | species) + (1 | plot), data = green_kbs, family = poisson)  
summary(modc)
```

Because no distributions seems to match well, I'll try a Friedman's test

```
# friedman_kbs <- green_kbs %>%  
# friedman_test(spp_half_cover_date ~ state)
```

Error: Must extract column with a single valid subscript. x Subscript var can't be NA

Can't figure out what this means

If I include the blocks portion of the formula (from the documentation) I get this error

```
# friedman_kbs <- green_kbs %>%  
# friedman_test(spp_half_cover_date ~ state | plot)
```

Error in friedman.test.default(c(141L, 202L, 122L, 101L, 127L, 120L, 197L, : not an unreplicated complete block design

Permanova?

```
per1 <- adonis2(green_kbs$spp_half_cover_date ~ state * year +  
  insecticide, data = green_kbs)  
per1  
per2 <- adonis(formula = green_kbs$spp_half_cover_date ~ state *  
  year + insecticide, strata = green_kbs$plot, data = green_kbs)  
per2
```

With per2, when controlling for “plot”, there is a difference btwn treatments

UMBS

Checking for normality

```
hist(green_umbs$spp_half_cover_date)
```

```
qqnorm(green_umbs$spp_half_cover_date)
```

Normal Q-Q Plot

```
shapiro.test(green_umbs$spp_half_cover_date)
```

```
##  
## Shapiro-Wilk normality test  
##  
## data: green_umbs$spp_half_cover_date  
## W = 0.92247, p-value < 2.2e-16
```

```
hist(green_umbs$spp_half_cover_date[green_kbs$state == "ambient"])
```

istogram of green_umbs\$spp_half_cover_date[green_kbs\$state == "am

green_umbs\$spp_half_cover_date[green_kbs\$state == "ambient"]

```
hist(green_umbs$spp_half_cover_date[green_kbs$state == "warmed"])
```

istogram of green_umbs\$spp_half_cover_date[green_kbs\$state == "wa

green_umbs\$spp_half_cover_date[green_kbs\$state == "warmed"]

These look pretty good

Trying log transformation

```
green_umbs$date_log <- log(green_umbs$spp_half_cover_date)
hist(green_umbs$date_log)
```

```
shapiro.test(green_umbs$date_log)
```

```
##
##  Shapiro-Wilk normality test
##
## data:  green_umbs$date_log
## W = 0.96356, p-value = 8.516e-13
```

I think this looks good but shapiro-wilk is lower than 0.05

Trying inverse tranformation

```
green_umbs$date_inv <- 1/(green_umbs$spp_half_cover_date)
hist(green_umbs$date_inv)
```

```
shapiro.test(green_umbs$date_inv)

##
##  Shapiro-Wilk normality test
##
## data:  green_umbs$date_inv
## W = 0.97928, p-value = 6.952e-09
```

This also looks good but is also still low for shapiro-wilk
